(12) INTERNATIONAL APPLICATION PUBLISHED UNDER THE PATENT COOPERATION TREATY (PCT)

(54) Title: SYSTEM FOR AND METHOD OF RELATIONAL DATABASE MODELING OF AD HOC DISTRIBUTED SENSOR NETWORKS
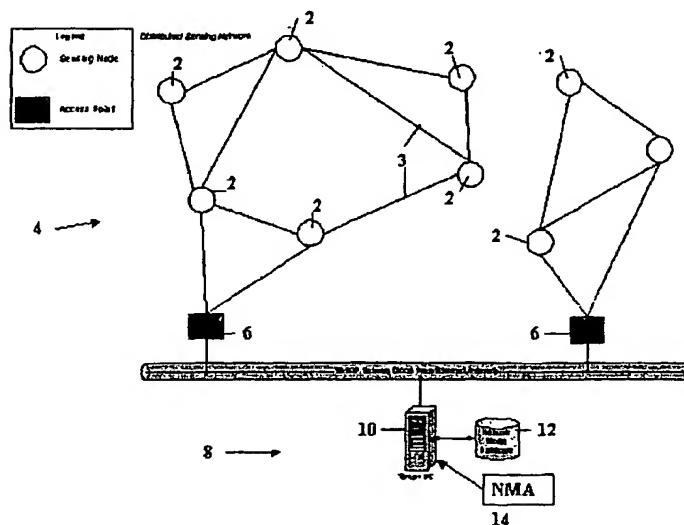

(57) Abstract: Method of and system for aggregating into a relational database model the state of an ad hoc network comprised of uniquely addressable distributed sensor nodes in communication using networking protocols with one another throgh links and to a database server through access points. A relational database logical design resident on the database server is dynamically updated with respect ot eh sensor network's current and historical topological information through the use of a traversal and interrogating network modeling agent. The distributed sensors nodes may be mobile, and may communicate by wired or wireless means through netorking protocols such as the Internet.

System for and Method of Relational Database Modeling of Ad Hoc Distributed Sensor Networks

This application claims priority to U.S. Provisional Application Ser. No.
5   60/262,226, filed January 17, 2001, which is incorporated herein by reference in its
entirety.

Field of the Invention

The present invention relates generally to distributed sensor network state
10   discovery and maintenance. More specifically, the invention employs a quasi-
recursive traversing and interrogating algorithm from a remote location to sensor
nodes in a network in order to construct and maintain a relationsal database model of
the sensor network on a database server.

Background of the Invention

15   There has been an exponential growth of Internet infrastructure related to
electronic data transfer. The expansion was due, in large measure, to what was
perceived as a new business model related to the dot.com explosion. The rapid
growth of the dot.com world squeezed 30 years of physical plant installation into a
five or ten year period. Some say that with the recent implosion of the dot.com world,
20   billions of dollars have been wasted. The Applicants contend that, in fact, this
valuable infrastructure, both physical and procedural, offers an enormous opportunity.
The new Internet infrastructure can be leveraged and real value can be harvested in
support of industry, the consumer sector, users of medical devices, and more. It is
precisely this opportunity that is the driving motivation behind the present invention.
25   Technology development in a number of disparate areas is enabling new
interdisciplinary approaches to solve long-standing problems. Three technologies of
particular interest are the miniaturization of sensors and actuators, wireless coupling
of these devices to enterprise information systems, and software for dynamic, real-
time access to remote systems over the Internet. What is needed is a means for
30   converging these technologies, in order to enable the transformation of disconnected

1

sensors generating reams of data into highly connected networks of sensors generating added value information. This convergence will permit organizations to connect all electronic sensing and actuation into a single, integrated information architecture.

5   The tools needed to implement the vision of seamless, global access to remote information are available only in part, and not yet as an integrated package. The Applicants describe below the development of an information architecture, which is referred to in certain embodiments as Intelemetric™, and a method of using the architecture which make it possible to aggregate, store, process, and distributed, real-

10   time distributed sensor data into the enterprise, and make resulting information readily available over the Internet.

Summary of the Invention

           In one aspect, the present invention is an information architecture that permits

15   the Internet to contact distributed sensors at one point, databases and mining engines at another point, and users at another point. In this aspect, the invention is an enabling interface between the Internet and the physical world. Due to the global reach of the Internet, these physical points of contact may be distributed anywhere in the world. The Applicants have invented a sensor network modeling agent for use with a

20   relational database and a logical design resident therein.

           In another aspect, the present invention is a method of database modeling that makes it possible to create, store, and update a virtual model of a network of sensors within a relational database structure. The network modeling agent dynamically updates various sensor node data and link data that collectively define an

25   instantaneous "state" of the sensor network into the database logical design. The network modeling agent thereby facilitates access, visualization, and the use of a stream of information generated by the network of distributed sensors. The sensor nodes to be interrogated by the network modeling agent are assumed to be uniquely addressable and in communication, using networking protocols, with one another

30   through links and with a database server through one or more access points. A method according to the present invention comprises the steps of discovering and maintaining the distributed sensor network topology by applying at every access point

a uqasi-recursive algorithm, which causes the network modeling agent to visit a first sensor node and mark the first node visited, push the marked first node onto a stack, and while the stack is non-empty, query the node at the top of the stack for a list of current links to the node at the top, compare the list of current links to a list of

5   historical links to the node at the top of the stack and update the historical link and historical node information, and if there are no unmarked nodes reachable from a current link then pop the stack, otherwise visit the next reachable unmarked node, mark the next node and push it onto the stack. The network modeling agent builds the database model by updating relational database logical design tables at each step of

10   the discovering step. The agent maintains the database model by periodically reapplying the interrogating algorithm, thereby updating the database model to account for sensor node and link additions and deletions. The periodicity of updates is preferably such that a near real-time topology of the sensor network is maintained.

In another embodiment, the present invention is a method as described above,

15   wherein the logical design tables further comprise a data table for mapping between one or more sensor nodes and the tables used to store the associated sensor output data associated with the one or more sensor nodes.

In certain embodiments, the present invention is used in modeling networks comprised of mobile sensor nodes. The sensor nodes may communicate by wired or

20   wireless means. The database server used with the present invention may be remotely located from the distributed sensor network.

Brief Description of the Drawings

Figure 1 is an illustration of a distributed sensor network in communication through

25   one or more access points to a IT infrastructure operating a network modeling agent according to the present invention.

Figure 2 is an illustration of the elements of a simple node.

Figure 3 is a block diagram of a database model logic design in accordance with the present invention.

30   **Figure 4** is an illustration of a portion of an alternative database model logic design embodiment of the present invention, including a Data Table List table.

Figure 5 is an illustration of a sensor network whose topolgy is discoverable by a network modeling agent.

Figure 6 is an illustration of the network modeling agent's discovery of a new sensor node in a sensor network.

5   **Figure 7** is an illustration of the network modeling agent's discovery of a missing or deleted sensor node in a sensor network.

Figure 8 is an illustration of the network modeling agent's discovery of a new link between existing sensor nodes in a sensor network.

Figure 9 is an illustration of the network modeling agent's discovery of a missing link

10   between existing sensor nodes in a sensor network.

Detailed Description of Certain Embodiments

Preferred embodiments of the invention will now be described with reference to the accompanying drawings.

Fig. 1 illustrates the environment in which the present invention may be

15   employed. Distributed sensing nodes **2** are connected to one another in a sensing network **4** through some kind of ad hoc networking protocol, with an attendant physical implementation (which may be wired or wireless). The topology of the network **4** is largely unconstrained, except that there exist a finite number of known access points **6** that comprise a bridge between the sensing network **4** and a

20   conventional information technology (IT) infrastructure such as a corporate LAN **8**. The access points **6** provide the means by which the information at each node **2** can be obtained from outside the network **4**. The access points **6** may even be implicit; the sensing network **4** could just as easily be a peer-to-peer arrangement on a conventional TCP/IP network. On the LAN **8** is a database server **10** includes a

25   network model database **12** and operates a network modeling agent (NMA) **14**. The NMA **14** is useful in creating a model of the instantaneous state of the sensing network **4**. The model created is comprised of the following data elements:

- an **identity** (unique identifying information such as a numeric address) of each of the sensing nodes **2** in the network **4**, as well as any metadata

30   about each node;

4

- a **connectivity** of each of the sensing nodes 2; i.e., a structural representation of the network topology that could be used to reconstruct a diagram such as **Fig. 1**;

- an up-to-date **information content** at each of the sensing nodes 2; i.e., a real-time snapshot and time-history of the data of interest generated at each node location by an attached suite of sensors 16, as depicted in **Fig. 2**; and

- a **history** of the network 4 from the moment the model was first constructed, which would allow a reconstruction of the network's state at any time in the past.

It is of no concern how this network topology came into being, how it is organized, what routing algorithms are used to pass messages from one node to the next, but rather, how to aggregate the information at each of the nodes into an off-network repository or network model database 12. The sensing nodes 2 may be mobile, and the interconnections may change over time. Furthermore, new nodes may join the network 4 at any time, and existing nodes may leave the network unexpectedly.

Fig. 2 illustrates the nature of each of the sensing nodes 2, which comprise computational devices (possibly ranging in complexity from small embedded platforms to a fully-fledged PCs) that have one or more sensors 16 providing high-value information connected to it. The term *sensor* is used here in a general sense. A sensor 16 as contemplated herein could be as simple as an instrument that measures temperature, pressure, or any such other physical quantity. It could also be a device as complex as a video camera providing continuous full-motion imagery of some area of interest. In any case, the output of each of these sensors 16 is stored locally in a well-defined *knowledge base* 18, but the output can be accessed from outside the network 4 through some software application programming interface (API) and hardware implementation. Each of the sensing nodes 2 is additionally in communication with one or more other sensing nodes through connecting links 3.

The following assumptions about each of the sensing nodes 2 are made:

- each node is addressable from the outside world or from other nodes;

5

- the structure and nature of the sensor(s) output data is known *a priori* or it can be retrieved by interrogating the node with which the sensor(s) are associated;

5

- each node contains some local memory or other knowledge base **18** for recording sensor output data, which can be retrieved by interrogating the node;

- each node uses networking protocols that allow it to communicate with its neighboring nodes in the ad hoc sensor network (again, it is of no import how the sensor network came into being, how its connectivity is specified,

10

or how nodes find one another); and

- each node is essentially a read-only device (no assumptions are made regarding the capability of each node to inform any agent running on the database server **10** to update its associated information.)

        With these constraints, we now describe the operation of the NMA **14** in

15   modeling the state of the network **4** within a conventional relational database **12**.
There are two key components to this problem: the relational database structure used
to encapsulate a complete, unambiguous description of the network **4**; and the means
by which the network model is built. Section 1 below describes a simplified database
structure, while Section 2 presents and describes the application of a quasi-recursive

20   algorithm for building the model.

Section 1: Database Representation

        Fig. 3 presents a candidate relational database logical design **19** for capturing
information about the sensor network **4**, comprising: a *node address* for each of the
sensing nodes **2** in the network,as shown in a Node Table **20**; each sensing node's

25   *connectivity* to other sensing nodes, as shown in a Links Table **22**; the information
content each node presents, as shown in one or more Node Data Table(s) **24**; and a
history of the network's state, as reflected in a Node History Table **28** and a Link
History Table **26**.

        Note that a skilled artisan will recognize that any practical implementation of

30   the logical design **19** would have many more problem-specific elements. Fig. 3 is not

6

intended to be limiting in any manner, but merely illustrative of the minimum requirements of a relational database logical design 19 in accordance with the present invention, specifically an embodiment in which each sensing node is collecting numeric data from n sensors.

5   The Nodes Table 20 maintains a list of all known sensor nodes 2 in the network 4. Each node is identified by a unique *Node Address*, which is a primary key for the Nodes Table 20. The Nodes Table also contains a *Status* field, which is used to indicate whether a node is known to be active. This field is used for marking nodes that have disappeared from the network (which could later reappear). At present, it is

10   anticipated that this *Status* variable will take on one of just a small set of mutually exclusive values that indicate whether or not the associated node continues to be an active, reachable member of the network 4. Finally, the Nodes Table 20 contains a *Timestamp* field that indicates when the *Status* information was last updated. When a node disappears from the network for whatever reason, the corresponding entry in the

15   Nodes Table 20 is not deleted; it is marked as unreachable. The reason for doing so is explained below.

By itself, the Nodes Table 20 is insufficient for characterizing the network's structure. Also required is a mechanism for specifying inter-node connectivity, which is provided by the Links Table 22. The primary key for the Links Table 22 is a unique

20   *Link ID* number for each link 3, said number can be generated automatically by modern relational DB software. The Link Table 22 also contains *Node Addresses* identifying the nodes at each end of each link 3, and a *Timestamp* that specifies when information about a link's existence was last updated. Certain constraints exist on the Links Table 22, which are enforced externally through the use of stored procedures.

25   Specifically, there can be only one entry in the Links Table 22 for a connection between any two nodes A and B. There cannot simultaneously be an entry {*ID*, A, B, *Timestamp*} and an entry {*ID*, B, A, *Timestamp*}. To enforce this constraint, we define a stored procedure to ensure link uniqueness when an attempt is made to enter a link definition into the Link Table 22.

30   Together, the Nodes Table 20 and Links Table 22 define the instantaneous topology of the sensor network 4. It is also desirable to be able to reconstruct the network structure at any point in the past. The Node History Table 28 and Link

7

History Table 26 provide this capability. When an entry is made or updated in the
Nodes table, a stored procedure is executed to generate an entry in the Node History
Table 28 automatically. This latter entry duplicates the information placed in the
Nodes Table 20, along with an *Action* field that captures whether new node

5   information was inserted, or the *Status* of an existing node was updated. Similarly,
when a new link is inserted into the Links Table 22 or an existing link is deleted, a
stored procedure inserts a record of that event in the Link History Table 26. Finally,
when an existing node is marked as unreachable, stored procedures automatically
delete any links to/from that node in the Links Table 22, and corresponding entries are

10   made in the Link History Table 26. Together, these two history tables make it possible
to reconstruct the past state of the sensor network at any desired point in time.

       The relational databse logical design 19 is further comprised of one or more
Node Data Tables 24 used to capture the actual information content from each node;
i.e., the sensor data output. This is highly problem-specific, because the *Sensor Data*

15   could range in complexity from periodic ambient temperature measurements to full-
motion MPEG video that streams from each node. Furthermore, each node could be
generating a different type of information, which would necessitate the definition and
instantiation of several different Sensor Data Tables 24, perhaps even more than one
per node (depending on the complexity of the information stream).

20   Fig. 3 illustrates the simplest case, wherein each node 2 generates *n* well-
defined sensor data signals. The composite primary key for the Sensor Data Table 24
is the identity of the *Node Address* and a *Timestamp*, followed by *n* individual sensor
data outputs. This ensures that the only allowable entries are for known nodes, and
that only one entry can be made per node at a given time instant. In this simple case,

25   all *Sensor Data* is stored in the same Sensor Data Table 24. Each node may have a
unique internal sampling rate, and the node itself may be sampled by the database
server 10 at different rates; no assumptions are made about these operations. The
relationship between this Sensor Data Table 24 and Nodes Table 20 illustrates why
entries on individual nodes are not deleted from the Nodes table when they become

30   unreachable: access to historical sensor data from past members of the network is
preferred, even if those members are no longer present.

In another embodiment, the database logical design 19 further comprises a Data Table List 30 that provides a mapping between individual nodes 2 and the names of the tables used to store those nodes' *Sensor Data*. Each of these tables is defined and created dynamically, based on the structure of the information at each node. Fig.

5   4 illustrates an embodiment of a network model logical design 19 for a three-node network configuration wherein each of the three nodes (A, B, C) provides a different amount of data. As such a network is traversed and the Nodes Table 20 is populated, an entry is made in the Data Table List Table 30 that identifies the name of the table associated with a given node. In the example illustrated, each node (A, B, C) has its

10   own Node Data Table (27A-C). Each of Node Data Table is defined to accommodate the type of sensor data known to originate from that node. As discussed earlier, it is assumed that the software agent on the database server can interrogate the node to determine what type of information it provides, and then define the table structures accordingly.

15   **Section 2: Network Traversal Algorithm**

To build the database representation of the sensor network 4 described above, the NMA 14 employs a means to traverse the network in order to interrogate each node. The NMA 14 employs a quasi-recursive algorithm that is run on the database · server 10 to build and maintain the database network model. The NMA 14 is a

20   software agent resident on the database server 10 and written in any compatible computer language, whose responsibility is to build and update this model. As discussed earlier, it is assumed that there exists some software API that allows the NMA 14 to access each node on the network, which is reached via one or more access points 6 that can be reached via Internet protocols from the database server 10.

25   To support creation and maintenance of the database model, the NMA 14 performs database updates in response to the following events:

- **Initial model construction**: When the database server 10 first establishes a connection with the sensor network 4, it must discover and build a model of that network's topology.

30   - **Node addition**: it is assumed that sensing nodes 2 can join the ad hoc sensor network 4 at any time. Sensing nodes are added to the network

when they form links 3 (i.e., bi-directional communication channels) with other nodes that are already part of the sensor network.

- **Node deletion:** Once the network 4 is established, its topology is not
  5   necessarily static. In the case of mobile nodes that communicate with one another wirelessly, a node may go out of range of all of its neighboring nodes and thus cease to be part of the network. Even in the case of fixed nodes, a node may be shut off and thus cease to be part of the network.

- **Link Addition:** New direct links may form between individual nodes even if the number and identity of the nodes in the network is fixed. The Lik
  10   Table 22 shown earlier must be updated accordingly to reflect the evolving topology.

- **Link deletion:** Links between any two nodes may cease to exist if the two nodes are unable to communicate with one another due, for example, to range limitations in a wireless network.

15   The next section describes a quasi-recursive depth first search algorithm that can be used to support the functions needed for handling all of these events. It then illustrates the application of the search algorithm to each of the events described above.

2.1   Algorithm Psuedo-Code

20   As described previously, it is assumed that there exist a finite number of known access points 6 to the sensor network 4. The search algorithm presented below is applied sequentially by the NMA 14 over all access points to build the network model.

Let x be the specified access point 6 (also a node) where the traversal of the
25   network 4 is to begin. Let N be the Node Table 20, NH be the Node History Table 28, L be the Link Table 22, and LH be the Link History Table 26 as described in the previous section. Let CAL be the list of links 3 discovered by querying the nodes 2, and HAL be the list of links discovered in the previous traversal. Let S be the stack for keeping track of the traversal, and $NUM(v)$ be the traversal order (i.e., sequence) of
30   the node v.

10

The NMA 14 building the network model invokes the *Traversal* function on each of the access points 6. This function uses the *Visit* and *Mark* functions shown subsequently in the course of its operations.

```
        Begin Sweep
5       Traversal (x: node)
                S ← Empty
                v ← x
                i ← 0
                Set all nodes in N as unmarked
10              Visit (v)
                Mark (v, i)
                push v into S
                while S is non-empty do
                        t ← the node at the top of the stack S
15                      CAL ← List of current links to t obtained by
        querying node t
                        HAL ← List of historical links to t obtained by
        querying existing database
                        Compare CAL and HAL. If different update L, LH, N,
20      NH tables
                        if there is no unmarked node w reachable from a
                link in CAL then
                                pop(S)
                                else
25                              for each unmarked node w reachable from a link in
                CAL   do
                                        i ← i + 1
                                        Visit(w)
                                        Mark (w, i)
30                                      Push w into S
                                end for
                                else if
                        end while
                end Traversal
35      for each unmarked node w in N   do
        Update NH table to indicate that node is unreachable
        end for
```

```
End Sweep

        Visit (w: node)
                Retrieve information in KB_w from node w
5               Update N
        end Visit

        Mark (v: node, i: id)
        Timestamp(v) ← current time
10              NUM(v) ← i
        end Mark
```

The operation of the NMA **14** in constructing and maintaining the network model, using the algorithm, will now be described.

2.2   Algorithm Walk-Through

In the following five subsections we illustrate the application of the network traversal algorithm to each of the event types described above. These "walk-throughs" describe how database tables are built and updated in response to events within the network.

2.2.1   Initial Construction of Network Model

Table 1 presents a walkthrough of the algorithm presented above, for building an initial model of the network illustrated in **Fig. 5**. The left portion of **Fig. 5** illustrates the topology of a network connected to a single access point **6**, while the right side shows the order of traversal. Observe that not all links **3** are traversed (though all are examined). This ensures that each node is visited just once during the model construction process.

Table 1 provides details of the process by which the network **4** is traversed. The first column of Table 1 shows the node stack maintained by the NMA **14**. The second column (*CAL*) shows the current links from the Node at the top of the stack. The third column (*HAL*) shows the links that were obtained from the node at the top of the node stack in a previous sweep of the entire network. The fourth column shows the actions performed inside the *for-loop* of the pseudo-code.

Table 1: Network Traversal Process for Initial Model Construction

Stack S	CAL	HAL	Action	Visit order

12

Stack S	CAL	HAL	Action	Visit order
-	-	-	Visit A, Push A	A = 0
A	{AB}{AC}	{AB}{AC}	Visit B, Push B Visit C Push C	B = 1 C = 2
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Visit G, Push G	G = 3
G C B A	{GC}{GE}{GF}	{GC} {GE}{GF}	Visit E, Push E Visit F, Push F	E = 4 F = 5
F E G C B A	{FE} {FG}	{FE} {FG}	Pop F	
E G C B A	{EF} {EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Visit D, Push D	D = 6
D E G C B A	{DE} {DB}	{DE} {DB}	Pop D	
E G C B A	{EF} {EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Pop E	
G C B A	{GC}{GE}{GF}	{GC}{GE}{GF}	Pop G	
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Pop C	
B A	{{BD} {BE}{BC}	{BD} {BE}{BC}	Pop B	

Stack S	CAL	HAL	Action	Visit order
A	{AB}{AC}	{AB}{AC}	Pop A	
-	-	-	Check for unreachable nodes. Finish.	

The traversal process begins at node A **32**. Node A **32** is visited and pushed onto the stack. The process of visiting a node involves retrieving the information stored at the node, and updating the local database.

5 Next, the NMA **14** examines the node at the top of the stack. If the stack is empty, the NMA **14** has completed traversal. If the stack is non-empty, the NMA **14** looks at the node at the top of the stack, and then queries the node for all its link information. On obtaining this information, the NMA **14** compares it to the link information obtained from the node in the previous sweep of the network. No

10 difference between the *CAL* and *HAL* for node A **32** is seen. The NMA **14** then examines each link **3** of the currently visited node and the node at the other end of the link. If the NMA **14** has not seen (marked) the node on the other end of the link before, it visits the node on the other end of the link and pushes it on the stack. The NMA **14** then marks the node as visited by assigning a visit order number to it, and by

15 assigning a *Timestamp* representing the time it was visited. In our example, *CAL* consists of links {AB} **33**, {AC} **35**. Nodes B **34** and C **36** are unmarked. The NMA **14** visits node B **34** and pushes it on the stack. The NMA then visits node C **36** and pushes it on the stack. By following a similar procedure, the NMA visits and marks nodes G **38**, E **40**, and F **42**. When node F **42** is at the top of the stack, there is no

20 node reachable from node F that has not been marked. Therefore, the NMA Pops Node F from the stack. When node E **40** reaches the top of the stack, the NMA discovers another node D **44** which has not been marked. The NMA visits it, and pushes it on the stack. At this point, node D **44** does not have links to any unvisited node. The NMA therefore pops D from the stack. Following the algorithm, the NMA

25 continues to pop nodes E, G, C, B, and A until an empty stack remains. At this point, the NMA checks the Node Table **20** to see if any node that was visited in a previous traversal of the network has become unreachable during this traversal. In this case there are no unreachable nodes. That completes a sweep of the network. The next sweep can now be scheduled.

14

2.2.2 *Adding a New Node*

Once an initial model of the sensor network has been constructed, new nodes may join the network at any time. The introduction of a new node is detected only when it forms links with its neighboring node(s), as shown in **Fig. 6**. In the example

5   presented, node H **46** forms links (**39, 41**) with nodes G **39** and E **40**. The network's topology is otherwise unchanged.

Assuming that nodes E **40**, G **38**, and H **46** are unaware of the interest that the database server **10** has in their information outputs, the NMA **14** is responsible for discovering any new network member(s). This implies that the NMA must perform

10   periodic network traversals to ensure that the database model is in sync with the true state of the network.

The addition of node H **46** changes the traversal sequence through the network. The NMA performs periodic traversals to detect such changes. The traversal proceeds as described above until node G **38** is at the top of the stack. At this time, a

15   new link {GH} **39** is discovered. Table 2 illustrates the new network traversal process. The differences from the traversal sequence of Table 1 are marked in bold. The discovery of a new link and node results in new entries into the Link Table **22** and Node Table **20**. Note that a check for the existence of the node and link is performed prior to making any additions. Node H **46** is then visited and pushed onto

20   the stack. Note also that the discovery of the new node changes the visit order for the various nodes.

Table 2: Network Traversal Process for Node Addition

Stack S	CAL	HAL	Action	Visit order
-	-	-	Visit A, Push A	A = 0
A	{AB}{AC}	{AB}{AC}	Visit B, Push B Visit C Push C	B = 1 C = 2
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Visit G, Push G	G = 3
G C B A	{GH} {GC} {GE} {GF}	{GC} {GE}{GF}	**Add {GH} to link table** **Add H to Node Table** **Visit H, Push H** Visit E, Push E Visit F, Push F	**H = 4** E = 5 F = 6

Stack S	CAL	HAL	Action	Visit order
F E H G C B A	{FE} {FG}	{FE} {FG}	Pop F	
E H G C B A	{EF} {EG} {EB} {ED} {EH}	{EF} {EG} {EB} {ED}	Visit D, Push D Add {EH} to link table	D = 7
D E H G C B A	{DE} {DB}	{DE} {DB}	Pop D	
E H G C B A	{EF} {EG} {EB} {ED}{EH}	{EF} {EG} {EB} {ED}	Pop E	
H G C B A	{HE}{HG}		Pop H	
G C B A	{GC}{GE}{GF}	{GC}{GE}{GF}	Pop G	
C B A	{CB} {CA} {CG}	{CB}{CA}{CG}	Pop C	
B A	{{BD} {BE}{BC}	{BD} {BE}{BC}	Pop B	
A	{AB}{AC}	{AB}{AC}	Pop A	

Stack S	CAL	HAL	Action	Visit order
-	-	-	Check for unreachable nodes. Finish.	

2.2.3 Deleting a Node

The network's topology changes when a node disappears from the network, as shown in **Fig. 7**. If individual nodes are mobile, a node can disappear if it is out of
5   range of all of its neighboring nodes, ceasing to be connected. A node also could be removed from the network if it suffers a system failure of some kind, or it is even possible that it may be programmed only to operate for a finite amount of time each day. Regardless of the cause, it becomes necessary to ensure that the database does not describe nodes that are no longer part of the network.

10   The loss or deletion of a node from the sensing network is similarly discovered during a periodic traversal for ensuring model integrity. Table 3 presents the traversal process for a case of node deletion. The traversal proceeds as previously describe until node G **38** is at the top of the stack. At this time, link {GF}**43** is discovered to be missing. This triggers the action of deleting link {GF} from the Link
15   Table **22**. Note that a check for the existence of the link is performed prior to any deletions are made. In a similar manner, link {EF} **45** is deleted from the Link Table **22**. At the end of the traversal, a check is made for any nodes that were unmarked. The node history table is updated to show that node F **42** is unreachable.

Table 3: Network Traversal Process for Node Deletion

Stack S	CAL	HAL	Action	Visit order
-	-	-	Visit A, Push A	A = 0
A	{AB}{AC}	{AB}{AC}	Visit B, Push B Visit C Push C	B = 1 C = 2
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Visit G, Push G	G = 3
G C B A	{GC}{GE}	{GC} {GE}{GF}	**Delete link {GF}** Visit E, Push E	E = 4

Stack S	CAL	HAL	Action	Visit order
E G C B A	{EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Delete link {E F} Visit D, Push D	D = 6
D E G C B A	{DE} {DB}	{DE} {DB}	Pop D	
E G C B A	{EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Pop E	
G C B A	{GC}{GE}	{GC}{GE}{GF}	Pop G	
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Pop C	
B A	{{BD} {BE}{BC}	{BD} {BE}{BC}	Pop B	
A	{AB}{AC}	{AB}{AC}	Pop A	
-	-	-	Check for unreachable nodes. Update node history table to show that F is unreachable. Finish.	

2.3.4   Adding a new Link between existing Nodes

The topology of the sensor network 4 can change even if the number of nodes remains fixed. For example, Fig. 8 illustrates a situation in which a new link {CE} 37

5   is formed between nodes C 36 and E 40. This could happen in a network of mobile nodes if two of the nodes come sufficiently close to one another that they establish

18

direct mutual communications. In the example shown, node C now has a link with node E, and vice versa. This new information must be captured in the database.

Table 4 illustrates the traversal process, with changes from the initial model construction traversal sequence marked in bold. The traversal proceeds as before until

5   node C 36 reaches the top of the stack. At this point, link {CE} 37 is discovered and added to the Link Table 22. Observe that this also changes the order of traversal of the nodes.

Table 4: Network Traversal Process for Link Addition

Stack S	CAL	HAL	Action	Visit order
-	-	-	Visit A, Push A	A = 0
A	{AB}{AC}	{AB}{AC}	Visit B, Push B	B = 1
			Visit C Push C	C = 2
C B A	{CB} {CA} {CE} {CG}	{CB} {CA} {CG}	**Add link {CE}** **Visit E, Push E** Visit G, Push G	E = 3 G = 4
G E C B A	{GC}{GE}{GF}	{GC} {GE}{GF}	Visit F, Push F	F = 5
F G E C B A	{FE} {FG}	{FE} {FG}	Pop F	
G E C B A	{GC}{GE}{GF}	{GC}{GE}{GF}	Pop G	
E C B A	{EF} {EG} {EB} {ED}{EC}	{EF} {EG} {EB} {ED}	Visit D, Push D	D = 6

19

Stack S	CAL	HAL	Action	Visit order
D E C B A	{DE} {DB}	{DE} {DB}	Pop D	
E C B A	{EF} {EG} {EB} {ED}{EC}	{EF} {EG} {EB} {ED}	Pop E	
C B A	{CB} {CA} {CG}	{CB} {CA} {CG}	Pop C	
B A	{{BD} {BE}{BC}	{BD} {BE}{BC}	Pop B	
A	{AB}{AC}	{AB}{AC}	Pop A	
-	-	-	Check for unreachable nodes. Finish.	

2.2.5   Deleting a Link between existing Nodes

The network's topology can change if links between nodes cease to operate, as shown in **Fig. 9**. In the example given, nodes A **32** and B **34** both lose their direct connection to node C **36**.

As before, the traversal algorithm described above is used to ensure that the database model reflects this change in sensor network configuration. In this case, the link deletions completely change the order of the traversal, as shown below in Table 5. When node A **32** is at the top of the stack, link {AC} **35** is discovered to be deleted. When node B **34** is at the top of the stack, the NMA **14** discovers that link {BC} **39** needs to be deleted from the links database.

Table 5: Network Traversal Process for Link Deletion

Stack S	CAL	HAL	Action	Visit order
-	-	-	Visit A, Push A	A = 0
A	{AB}	{AB}{AC}	**Delete link {AC}** Visit B, Push B	B = 1
B A	{BA} {BD} {BE}	{BC} {BA}{BD} {BE}	**Delete link {BC}** Visit D, Push D Visit E, Push E	D = 2 E = 3

Stack S	CAL	HAL	Action	Visit order
E D B A	{EF} {EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Visit F, Push F Visit G, Push G	F = 4 G = 5
G F E D B A	{GC}{GE}{GF}	{GC}{GE}{GF}	Visit C, Push C	C = 6
C G F E D B A	{CA} {CG}	{CB} {CA} {CG}	Pop C	
G F E D B A	{GC}{GE}{GF}	{GC}{GE}{GF}	Pop G	
F E D B A	{FE} {FG}	{FE} {FG}	Pop F	
E D B A	{EF} {EG} {EB} {ED}	{EF} {EG} {EB} {ED}	Pop E	
D B A	{DE} {DB}	{DE} {DB}	Pop D	
B A	{BD} {BE}	{BD} {BE}{BC}	Pop B	
A	{AB}	{AB}{AC}	Pop A	
-	-	-	Check for unreachable nodes. Finish.	

21

Other embodiments of the invention will be apparent to those skilled in the art from a consideration of the specification or practice of the invention disclosed herein. It is intended that the specification and examples be considered as exemplary only, with the true scope and spirit of the invention being indicated by the following claims.

5   What is claimed is:

1 1.   A method of aggregating into a relational database model the state of an ad

2   hoc network comprised of uniquely addressable distributed sensor nodes in

3   communication using networking protocols with one another through links

4   and to a database server through access points, comprising the steps of:

5

6   providing a relational database logical design resident on the database

7   server in communication with the distributed sensor network, wherein

8   the logical design is comprised of one or more tables specifying sensor

9   node identities and node activity indicators, timestamping information,

10   link identification, linked nodes information, historical link

11   information, historical node information, and acquired sensor output

12   data;

13

14   discovering the distributed sensor network topology by applying at

15   every access point an interrogating algorithm further comprising the

16   steps of

17   visiting a first node,

18   marking the first node visited,

19   pushing the marked first node onto a stack, and

20   while the stack is non-empty,

21   querying the node at the top of the stack for a list of

22   current links to the node at the top,

23   comparing the list of current links to a list of historical

24   links to the node at the top of the stack and updating the

25   historical link and historical node information, and if

26   there are no unmarked nodes reachable from a current

27   link then pop the stack,

28   otherwise visiting the next reachable unmarked node,

29   marking the next node and pushing it onto the stack;

30

1		building a database model of the distributed sensor network by
2		updating the relational database logical design tables at each step of the
3		discovering step;
4		
5		maintaining the database model by periodically reapplying the
6		interrogating algorithm, thereby updating the database model to
7		account for sensor node and link additions and deletions.
8		
9	2.	The method of claim 1, wherein the distributed sensor nodes comprise mobile
10		nodes.
11		
12	3.	The method of claim 1, wherein the database server is in communication with
13		the distributed sensor network through wired means.
14		
15	4.	The method of claim 1, wherein the database server is in communication with
16		the distributed sensor network through wireless means.
17		
18	5.	The method of claim 1, wherein the database server is in communication with
19		the distributed sensor network via the Internet.
20		
21	6.	The method of claim 1, wherein the database server is located remotely from
22		the distributed sensor network.
23		
24	7.	The method of claim 1, wherein the periodicity of reapplying the interrogating
25		algorithm approximates real-time updating of the distributed sensor network
26		state.
27		
28	8.	The method of claim 1, wherein the logical design further comprises data table
29		information for mapping between one or more sensor nodes and the tables
30		used to store the associated sensor output data associated with the one or more
31		sensor nodes.

1

2   9.   A network modeling agent for aggregating into a relational database model the

3   state of an ad hoc network comprised of uniquely addressable distributed

4   sensor nodes in communication using networking protocols with one another

5   through links and to a database server through access points, the network

6   modeling agent comprising:

7

8   a relational database logical design resident on the database server in

9   communication with the distributed sensor network, wherein the

10   logical design is comprised of one or more tables specifying sensor

11   node identities and node activity indicators, timestamping information,

12   link identification, linked nodes information, historical link

13   information, historical node information, and acquired sensor output

14   data;

15

16   computer code executable on the database server for executing at every

17   access point the steps of:

18   discovering the distributed sensor network topology by

19   visiting a first node,

20   marking the first node visited,

21   pushing the marked first node onto a stack, and

22   while the stack is non-empty,

23   querying the node at the top of the stack for a

24   list of current links to the node at the top,

25   comparing the list of current links to a list of

26   historical links to the node at the top of the stack

27   and updating the historical link and historical

28   node information,

29   and if there are no unmarked nodes reachable

30   from a current link then pop the stack,

1
2
3
4
5
6
7
